ABSTRACT

shown that in some cases even with full use of the variation principle,

good accuracy of the ground state wave function does not imply corre-

It is pointed out that if one uses an approximate ground state wave function in the familiar variational principle for the second-order energy, that the approximate energy need have no special relation-ship to the exact energy (it may be larger or smaller). Further it is

Aut hor

sponding accuracy of the approximate energy.

\*This research was supported by the following grant: National Aeronautics and Space Administration Grant NsG-275-62.

In situations where one wishes to know a second-order energy correction  $E^{(2)}$ , but does not have an accurate solution to the zero-order problem, a frequently used technique  $^1$  is to use as an approximation to  $E^{(2)}$  the quantity  $\mathfrak{T}$  where

$$\widetilde{J} = (\widetilde{\psi}_{0}, (V - \widetilde{E}^{(0)})\widetilde{\psi}^{(0)}) + (\widetilde{\psi}^{(0)}, (V - \widetilde{E}^{(0)})\widetilde{\psi}_{0}) + (\widetilde{\psi}^{(0)}, (H_{0} - \widetilde{F}_{0})\widetilde{\psi}^{(0)})$$
(1)

Here  $\widetilde{\Phi}_{0}$  is an approximate wave function for the zero-order problem (we will assume throughout that we are dealing with the ground state),  $H_{0}$  the zero-order Hamiltonian, V the perturbation,  $\widetilde{E}_{0} \equiv (\widetilde{\Phi}_{0}, H_{0}, \widetilde{\Phi}_{0})$ ,  $\widetilde{E}^{(1)} \equiv (\widetilde{\Phi}_{0}, V, \widetilde{\Phi}_{0})$  and  $\widetilde{\Psi}^{(1)}$  is to be determined variationally from  $\widetilde{\delta} \widetilde{J} = 0$ .

If we vary  $\tilde{\psi}^{(i)}$  freely (in practice of course one is rarely able to do this) then one is led to a differential equation for the "exact"  $\tilde{\psi}^{(i)}$ ;

$$(H_0 - \widetilde{E}_0) \widetilde{\psi}^{(i)} + (V - \widetilde{E}^{(i)}) \widetilde{\Phi}_0 = 0 .$$
 (2)

We will denote the solution of this equation by  $\psi^{(\cdot)}$  and the value of  $\tilde{J}$  to which it leads by J. One then readily finds successively that

$$T = (\widetilde{\mathfrak{F}}_{0}, (\mathbf{v} - \widetilde{\mathbf{E}}^{(\prime)}) \psi^{(\prime)}) = \sum_{m} (\widetilde{\mathfrak{F}}_{0}, (\mathbf{v} - \widetilde{\mathbf{E}}^{(\prime)}) \Phi_{m}) (\Phi_{m}, \psi^{(\prime)})$$
(3)

$$=\sum_{n}\frac{\left|\left(\widetilde{\phi}_{0},\left(V-\widetilde{E}^{(1)}\right)\varphi_{n}\right)\right|^{2}}{\widetilde{E}_{0}-E^{n}}$$
(4)

where we have introduced the eigen states of  $H_0$ :  $H_0 \Phi_m = E_m \Phi_m$ .

Further if we write a general  $\widetilde{\psi}^{(i)}$  as  $\widetilde{\psi}^{(i)} = \psi^{(i)} + \delta \psi^{(i)}$  then one has immediately that

$$\widehat{J} - J = (\delta + "), (H_0 - \widehat{E}_0) \delta + ")$$
 (5)

From Eq. (2) and (3) we then have the well-known result that if  $\Phi_0 = \Phi_0$  (and hence  $E_0 = E_0$ ) then  $T = E^{(1)}$ , and Eq. (5) then expresses the well known fact that under these same conditions an arbitrary  $T^{(1)}$  yields a T which is an upper bound to J and hence to  $E^{(2)}$ .

In this note we wish to discuss the relationships among J,  $\widetilde{J}$  and  $E^{(2)}$  in the more realistic case  $\widetilde{\mathfrak{G}} \neq \widetilde{\mathfrak{G}}$ . First, concerning the relationship between J and  $\widetilde{J}$  it follows immediately from Eq. (5) that J in general is <u>not</u> a lower bound to  $\widetilde{J}$  since a possible  $\delta \stackrel{\iota}{\downarrow}^{\iota}$  is certainly an arbitrary multiple of  $\widetilde{\mathfrak{G}}$ . Thus in general  $\delta \widetilde{J} = 0$  simply yields a stationary point although, of course, if, as is often the case in practice, one is dealing with a  $\widetilde{J}$  of <u>restricted</u> variability, it is quite possible that  $\delta \widetilde{J} = 0$  may in fact appear to yield a minimum.

We will not attempt a general discussion of the relationship between J and  ${\tt E}^{(2)}$ , but instead turn to two simple examples. In each  ${\tt H}_{\tt O}$  describes a one-dimensional harmonic oscillator

$$H_0 = \frac{P^2}{2m} + \frac{1}{2}m\omega^2 x^2$$

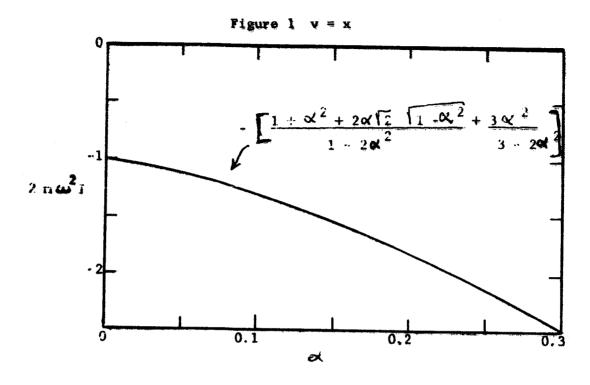

In example I, V=X while in example II,  $V=\frac{1}{2}X^2$ . These problems are readily solved exactly and yield, respectively,  $E^{(2)}=-1/(2\omega \omega^2)$  and  $-\frac{1}{16}/(16\omega^2\omega^3)$ 

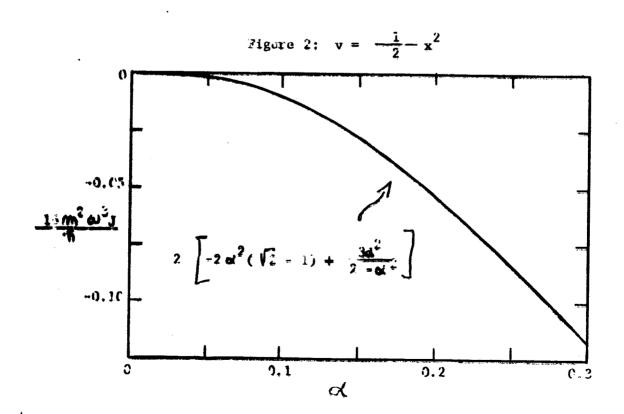

For each example we have evaluated J from equation (4) for  $\frac{1}{4}$  given by

The results of the calculation are shown in figures I and II. Let us first discuss example I. Here the important result is that  $J \leq E^{(2)}$  not  $J \in E^{(2)}$  for the range of X shown (see footnote 4). For other values of X between  $\pm 1$  one can get J values arbitrarily larger or smaller than  $E^{(2)}$ . When coupled with our earlier remarks on the relationship between T and J we have the obvious moral-anything can happenand we will not belabor the point further.

Now we turn to example II. Here we find  $J \nearrow E^{(2)}$  but in a curious way, namely even for  $\alpha=0$ ,  $J+E^{(2)}$ , and in fact for  $\alpha=0$  we have the largest deviation from  $E^{(2)}$ . The source of this peculiar behavior is not hard to find; it is in the M=0 term in Eq. (4), which from Eq. (3) can also be written as  $(\overleftarrow{\phi}_0, (v-\overleftarrow{E}^{(1)}) \overleftarrow{\phi}_0 X \overleftarrow{\phi}_0, \psi^{(1)})$ . For  $\alpha=0$  this term appears as the indeterminant form 0/0. However if one starts with  $\alpha=0$  initially then, as is well known, Eq. (2) does not determine  $(\overleftarrow{\phi}_0, \psi^{(1)})$ , any finite value is allowed, while on the other hand  $(\overleftarrow{\phi}_0, (v-\overleftarrow{E}^{(1)}) \overleftarrow{\phi}_0) \equiv 0$  whence 0/0 is to be read as 0, and we have the familiar result for  $E^{(2)}$ . On the other hand one sees that if one starts with  $\alpha\neq 0$  then  $(\overleftarrow{\phi}_0, \psi^{(1)})$  is determined and in fact is proportional to  $1/\alpha$  so that in the limit  $\alpha \rightarrow 0$  we find that 0/0 is to be read as a certain finite number. Hence the discrepancy. The moral here then is, in problems for which  $(\overleftarrow{\phi}_0, v \overleftarrow{\phi}_0)$  are not identically zero (they were

We are indebted to Dr. Margaret Benston for several helpful discussions.

- See for example T. P. Das and R. Bersohn, Phys. Rev., <u>115</u>, 897 (1959)
   and M. Karplus and H. J. Kolker, J. Chem, Phys., <u>38</u>, 1263 (1963).
   The latter authors also discuss various alternative procedures.
- We discuss the indeterminate M=0 term in Eq. (4) at the end of this note.
- 3. This is presumably what Das and Bersohn (reference 1) have in mind in the discussion following their Eq. (13) (which is identical to our Eq. (5)).
- 4. In order that  $\Phi_0$  have no nodes and go monotonically to zero as |x| increases,  $\alpha$  must be restricted to  $0 \le \alpha \le \frac{1}{3} \sqrt{\frac{2}{3}}$  (with the usual definition of the  $\Phi_m$ ).
- 5. If one redefines  $E^{(1)}$  as  $E^{(1)} = (\phi_0, \sqrt{\phi_0})$ , which also makes  $(\phi_0, \psi^{(1)}) = 0$ , then one gets proper behavior at d = 0 and a graph like that of figure I. However this is not a practical way out since by hypothesis we don't know  $\phi_0$ .
